Our Relationship with Data

How did we get here?

What's stopping us?

OPEN DATA FORMULA

CHALLENGE: The formula for discoverable data is clear, the formula to change human and organizational behavior is not.

ARCHITECT

STRUCTURAL

MECHANICAL

CONTRACTOR

How do you “view” a wall?

APPLICATION

Massing
Costing
Etc.

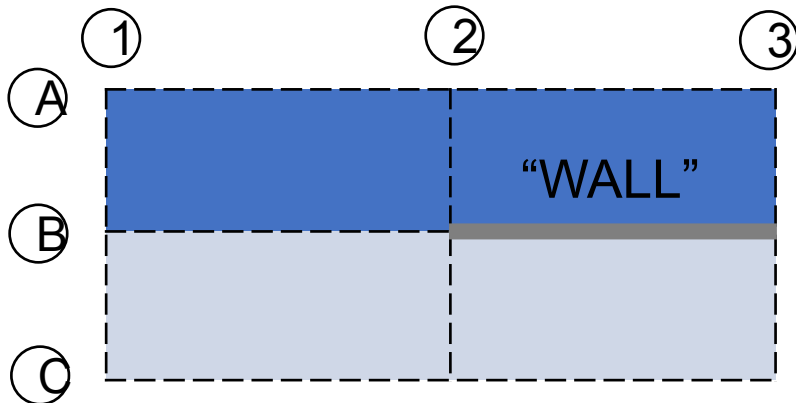

ABSTRACTION

“wall”= [Volume]

Finishes
Load Projection
Etc.

“wall”= [Area]

Relative Position
Stiffness
Etc.

“wall”= [Line]

CHALLENGE: We need to work with different “views”

CHALLENGE: We all “view” data differently

CHALLENGE: (1) Data is dynamic; (2) Data is distributed

How will we get there?

W3C/OGC Best Practices

“...link your data to other data to provide *context*.”

Best Practice 1: Use globally unique persistent HTTP URIs for Spatial Things

Use stable HTTP URIs to identify Spatial Things, re-using commonly used URIs where they exist and it is appropriate to do so.

Why

To publish [spatial data](#) on the Web, we need to stitch the [Spatial Things](#) and their corresponding entities into the Web's information space; contributing to the *Web of data*. First: [\[WEBARCH\] Good Practice: Identify with URIs](#) states that "agents should provide URIs as identifiers for resources". Second: the [5 Star Data scheme](#) states: "★★★★★ use URIs to denote things, so that people can point at your stuff".

Resources identified with HTTP URIs can be specified as the target of [links](#) within the Web's global information space, enabling information to be related, combined and referred to. This is the fundamental basis of 5★ Linked Data: "★★★★★ link your data to other data to provide context".

The HTTP URIs used to identify [Spatial Things](#) need to be stable or persistent so that relationships that link them to other resources don't break.

Intended Outcome

Spatial Things become part of the Web's global information space enabling them be linked with other [Spatial Things](#) and other resources and for those [links](#) to be durable. In other words, [spatial data](#) becomes part of the Web of Data.

Standards based on “Knowledge Graphs”

The Hazardous Situation Ontology Design Pattern

Agnieszka Lawrynowicz¹ and Ilona Lawniczak¹

Institute of Computing Science, Poznan University of Technology, Poznan, Poland

Abstract. This extended abstract describes an ontology for modeling hazardous situations. We build upon standards for hazards and hazardous events, and on existing standards of occupational safety. We also present an example of the pattern in the occupational safety and health domain.

Key words: ontology design pattern, ODP, hazards, occupational safety and health

2 Agnieszka Lawrynowicz and Ilona Lawniczak

Problem: Pattern mainly concerned with “Hazardous Event” for first response applications.

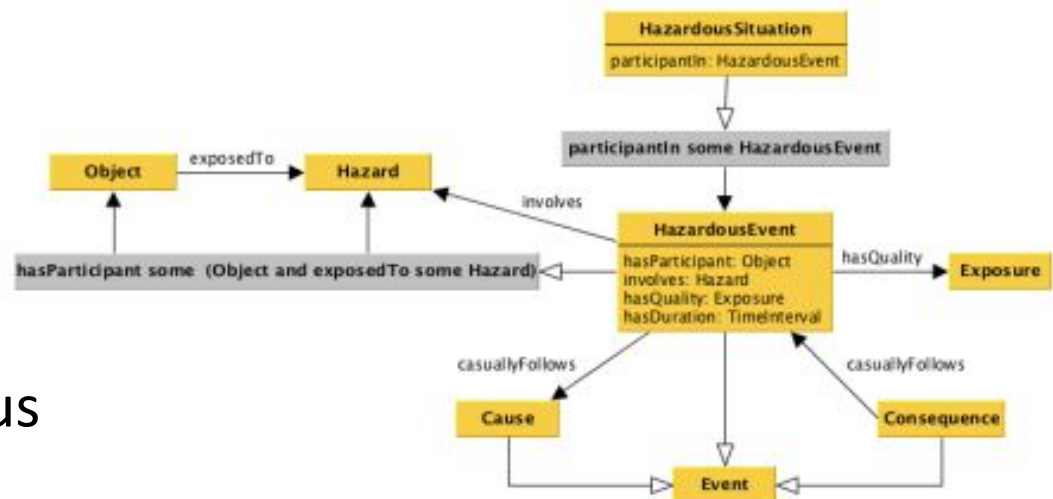

Fig. 1. The Hazardous Situation Ontology Design Pattern

Patterns are Extensible

A Modification to the Hazardous Situation ODP to Support Risk Assessment and Mitigation

Michelle Cheatham¹, Holly Ferguson², Charles Vardeman II², and Cogan Shimizu¹

¹ Wright State University

{michelle.cheatham,cogan.shimizu}@wright.edu

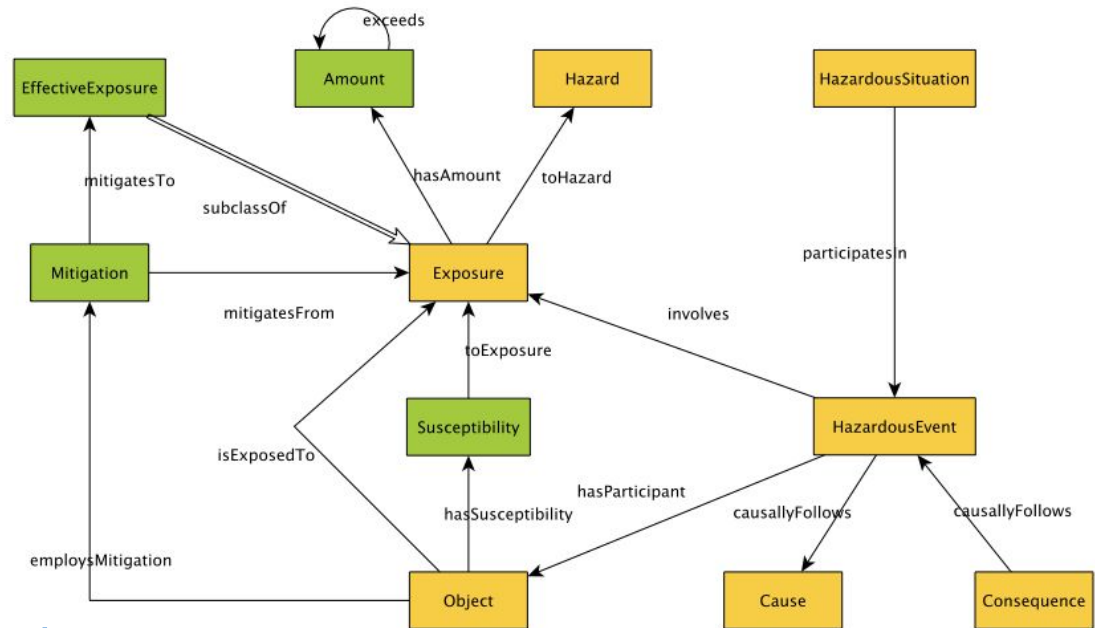

² University of Notre Dame

{hfergus2,cvardema}@nd.edu

Abstract. The Hazardous Situation ontology design pattern models the consequences of exposure of an object to a hazard. In its current form, the ODP is well suited for representing the consequences of exposure after the fact, which is very useful for applications such as damage assessment and recovery planning. In this work, we present a modification to this pattern that enables it to additionally support proactive questions central to risk assessment and mitigation planning.

Keywords: hazard, ontology design pattern, risk assessment, risk mitigation

SWEET Ontologies

chat on slack on channel #sweetontology

Introduction

Official repository for Semantic Web for Earth and Environmental Terminology (SWEET) Ontologies.

What is SWEET?

SWEET is a highly modular ontology suite with ~6000 concepts in ~200 separate ontologies covering Earth system science. SWEET is a mid-level ontology and consists of nine top-level concepts that can be used as a foundation for domain-specific ontologies that extend these top-level SWEET components. SWEET's own domain-specific ontologies, which extend the upper level ontologies, can provide users interested in further developing a particular domain with a solid set of concepts to get started. SWEET ontologies are written in W3C Turtle; the Terse RDF Triple Language and are publicly available under the Apache License v2.0.

Swiss Government and Localities

National Level

The screenshot shows the 'geo.admin.ch - the federal geoportal' website. The main navigation bar includes 'Current', 'geodata', 'cards', 'Thematic geoportals', 'Services', 'Research and Teaching', and 'Via geo.admin.ch'. The 'Services' menu is expanded to show 'Home page > Services > Geoservices > Linked data service'. The 'Linked data service' is selected, and the page title is 'Linked data service: semantically link geodata'. Below the title is a map of Switzerland with a network of grey lines and circles representing linked data. The text below the map explains that linked data uses the internet (web) to connect related data, identified, shared, and linked using URIs, and that standards like SPARQL are used to encode and link the data.

Home page > Services > Geoservices > Linked data service

Linked data service: semantically link geodata

Linked data uses the internet (web) to connect data that is related. The data are identified, shared and linked using the Uniform Resource Identifier (URI). The Resource Description Framework (RDF) and underlying standards such as SPARQL are used to encode and link the data.

sample queries

- [Five most populous municipalities \(graphic\)](#)
- [Administrative units at the coordinates 7.43, 46.95](#)
- [Districts by canton and year](#)
- [All versions of the resource by URI](#)
- [Corresponding resource in Wikidata and GeoNames \(community\)](#)
- [Five highest stops:](#)
- [Stops above 3000 meters above sea level. Sea:](#)
- [Stops with means of transport = cog railway, ship](#)

Local Level

 **Stadt Zürich** Linked Data

<https://ld.stadt-zuerich.ch/sparql/>

Open-Source Linked Data Interfaces

Zazuko Trifid Interface provides both human and machine (JSON-LD) accessible interfaces using linked data “follow your nose” principles.
Competency Question: “What is the corresponding resource in Wikidata and Geonames”?

The screenshot shows the Zazuko Trifid interface. At the top, there is a search bar with the URL `https://ld.geo.admin.ch/query`. Below it, a SPARQL query is displayed in a code editor. The query is a competency question designed to find Wikidata and Geonames URIs for a given municipality. The query is as follows:

```
1 PREFIX rdf: <http://www.w3.org/1999/02/22-rdf-syntax-ns#>
2 PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>
3 PREFIX wdt: <http://www.wikidata.org/prop/direct/>
4 PREFIX wikibase: <http://wikiba.se/ontology#>
5 PREFIX skos: <http://www.w3.org/2004/02/skos/core#>
6 PREFIX xsd: <http://www.w3.org/2001/XMLSchema#>
7 PREFIX wd: <http://www.wikidata.org/entity/>
8 PREFIX fn: <http://www.w3.org/2005/xpath-functions#>
9 PREFIX gn: <http://www.geonames.org/ontology#>
10 PREFIX schema: <http://schema.org/>
11
12 SELECT ?Municipality ?Name ?WikidataURI ?GeoNamesURI WHERE {
13   ?Municipality a <http://schema.org/AdministrativeArea> . #specify only the non-versioned entries.
14   ?Municipality <http://schema.org/name> ?Name .
```

Below the query, there are tabs for 'Table', 'Response', 'Pivot Table', 'Google Chart', and 'Geo'. The 'Table' tab is selected, showing a table with 10 rows of results. The table has columns for 'Municipality', 'Name', 'WikidataURI', and 'GeoNamesURI'. The first row is:

Municipality	Name	WikidataURI	GeoNamesURI
https://ld.geo.admin.ch/boundaries/municipality/4551	Aadorf	http://www.wikidata.org/entity/Q69131	http://sws.geonames.org/7285012/

Designing a Linked Data developer experience

Making decentralized Web app development fun.

WHILE THE SEMANTIC WEB COMMUNITY WAS FIGHTING ITS OWN INTERNAL BATTLES, we failed to gain traction with the people who build apps that are actually used: *front-end developers*. Ironically, Semantic Web enthusiasts have failed to focus on the *Web*; whereas our technologies are delivering results in specialized back-end systems, the promised intelligent end-user apps are not being created. Within the *Solid* ecosystem for decentralized Web applications, Linked Data and Semantic Web technologies play a crucial role. Working intensely on *Solid* the past year, I realized that designing a fun *developer experience* will be crucial to its success. Through dialogue with front-end developers, I created a couple of JavaScript libraries for easy interaction with complex Linked Data—without having to know *RDF*. This post introduces the core React components for *Solid* along with the *Ldflex* query language, and lessons learned from their design.

Australian Gov't Loc-I

<http://locationindex.org/>

Home | Benefit | Project Partners | Project Progress | Datasets | Linksets | Definitional Items | Tools | DGGS | Linked Project | Contact | Application

Purpose

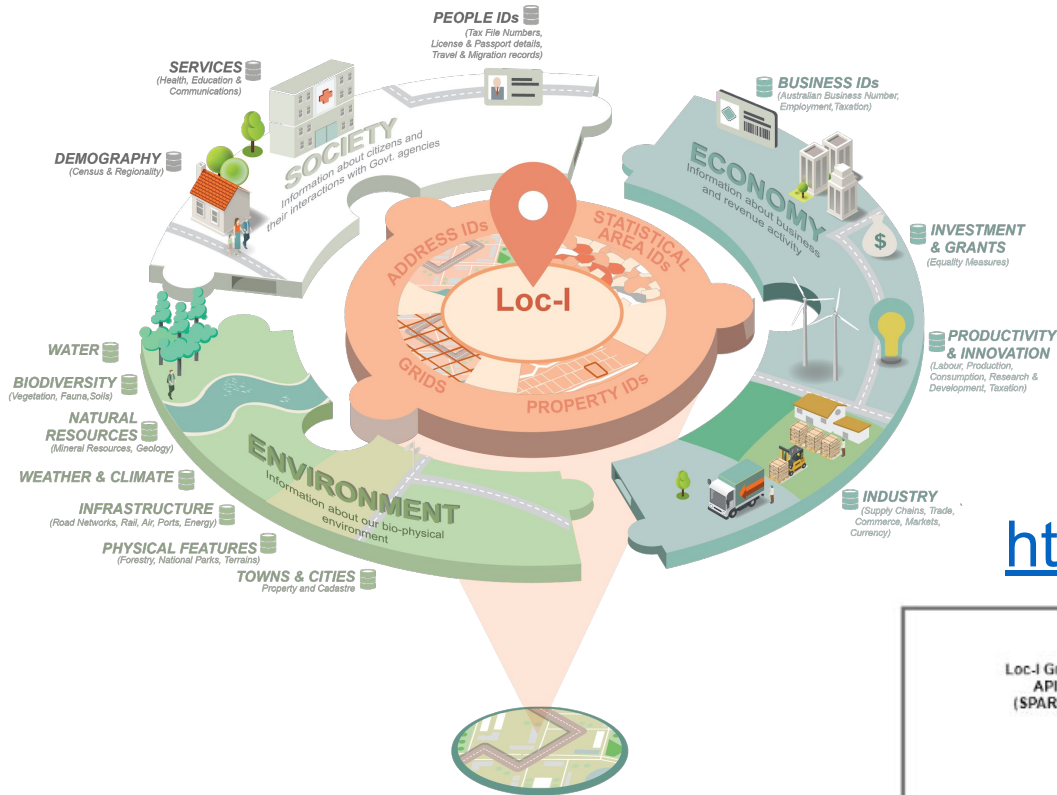

Location Index (Loc-I) is a framework that provides a consistent way to seamlessly integrate data on people, business, and the environment. Location Index aims to extend the characteristics of the foundation spatial data of taking geospatial data (multiple geographies) which is essential to support public safety and wellbeing, or critical for a national or government decision making that contributes significantly to economic, social and environmental sustainability and linking it with observational data. Through providing the infrastructure to support cross-domain foundation data linkages and analysis will open up substantial opportunity for providing a richer set of information to develop, analyse and evaluate policy, programs and service delivery by government.

The following video covers the purpose of the project

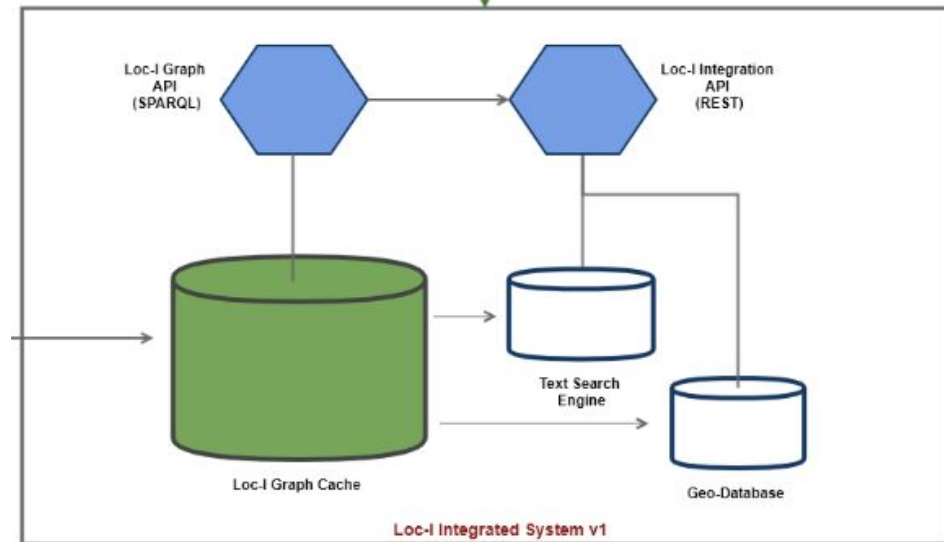

Demonstration Project: Natural disaster forecasting capability. Linking the National Exposure Information System with the Multi-Agency Data Integration Project (MADIP) and Business Longitudinal Analysis Data Environment (BLADE)

Loc-I Hybrid Approach

<https://tinyurl.com/sbq3tjq>

GEOSPATIAL DATA IN THE WEB

To publish data *in the Web*, we first have to identify the items of interest — those concepts, topics, events, communities, organizations, people, phenomena, features, datasets, applications, and services that are relevant to us. All items of interest are called *resources*. These are the things whose properties and relationships we want to describe and manage in the *Web of Data*.

GeoPlatform.gov aggregates, indexes, and links resources of the National Spatial Data Infrastructure (NSDI) to facilitate public and cross-government sharing, discovery, and access, of managed collections of authoritative and other relevant geospatial data. These are the things we are interested in curating, finding, and exploiting. The [GeoPlatform Portfolio](#) is a collection of resources of various types, roles, and interrelationships that have been curated for rapid access and use online.

The GeoPlatform Portfolio is managed as Linked Data on the Web. Linked Data enables people and software to share *structured data* and other related resources on the Web as easily as they can share *documents* today. The term Linked Data was coined by Tim Berners-Lee in his [Linked Data Web Architecture note](#). The term refers to a style of publishing and interlinking structured data on the Web. The basic assumption behind Linked Data is this: *the value and usefulness of data increases the more it is interlinked with other data*. In summary, Linked Data is simply about using the Web to create typed links between data from different sources so that relevant data can be more easily found, accessed, and exploited. This is what the GeoPlatform does.

Follow the references below for more information about the Semantic Web, Linked Open Data, and Spatial Data *in the Web*.

How is Resilience Data Used by Communities?

Knowledge Graph, Linked Data Approach Combined with Neural Network Based Approach

Collaboration with NOAA

- Initial focus on coastal inundation and community resilience, working with NOS
- Develop reusable dataset discovery services, so that the public and researchers can find trustworthy, high-impact data
- Identify experts who have used the data and the associated research topics, associated analytical methods and tools, and related datasets (e.g., Zillow, EPA, NASA, FEMA, etc.)
- Generalize for other federal agencies, such as USDA and NSF, as well as to international organizations, such as Deutsche Bundesbank
- Bring in AI expertise from industry and academia: KAIST, LARC, Recognai, DLA, Primer AI, GESIS, AllenAI, etc.

Administrative Data Research Facility

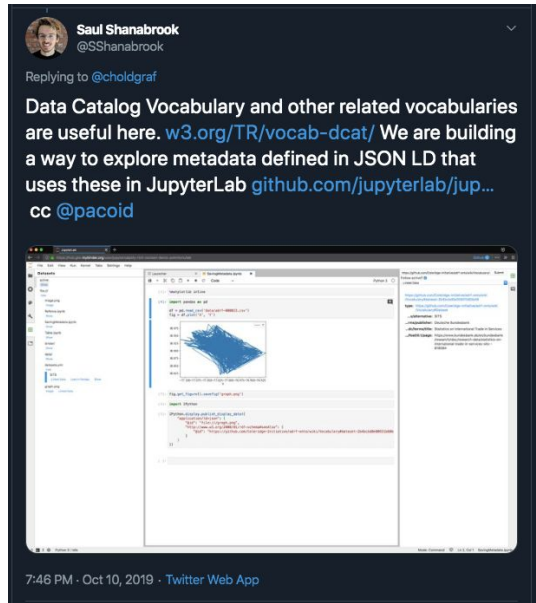

Coleridge Initiative

Julia Lane, et al. NYU Wagner

- FedRAMP-compliant **ADRF framework** on AWS GovCloud: “public agency capacity to accelerate the effective use of new datasets”
- for research projects using cross-agency sensitive data, in US and EU – **now in use by 30+ agencies**
- cited as the first federal example of Secure Access to Confidential Data in the final report of the Commission on **Evidence-Based Policymaking**
- augments **Data Stewardship** practices; collaboration with Project Jupyter on the related **data gov features**

<https://tinyurl.com/vsq6q9g>

Integration of Knowledge Graphs into Computational Toolchains

<https://twitter.com/SShanabrook/status/1182442214980501505>

Emerging category: watch the “AI Natives”

Projects (mostly OSS) that leverage **knowledge graph** of metadata about datasets and their usage:

- **Amundsen** @ Lyft
data discovery and metadata
- **Data Hub** @ LinkedIn
data discovery and lineage
- **Marquez** @ Stitch Fix
collect, aggregate, visualize metadata
- **UMS** @ Uber
manage metadata about datasets
- **Metcat** @ Netflix
data discovery, metadata service
- **Dataportal** @ Airbnb
integrated data-space (not OSS)

Funded additions to Project Jupyter

Make datasets and projects top-level constructs, support metadata exchange and privacy-preserving telemetry from notebook usage:

- JupyterLab **Commenting** and real-time collab similar to Google Docs
- JupyterLab **Data Explorer**: register datasets within research projects
- JupyterLab **Metadata Explorer**: browse metadata descriptions, get recommendations through knowledge graph inference (via extension)
- **Data Registry** (original proposal)
- **Telemetry** (privacy-preserving, reports usage)

W3C Prov-O Ontology Model

The properties `rdf:type` and `rdfs:label` are used to express [prov:type](#) and [prov:label](#), respectively.

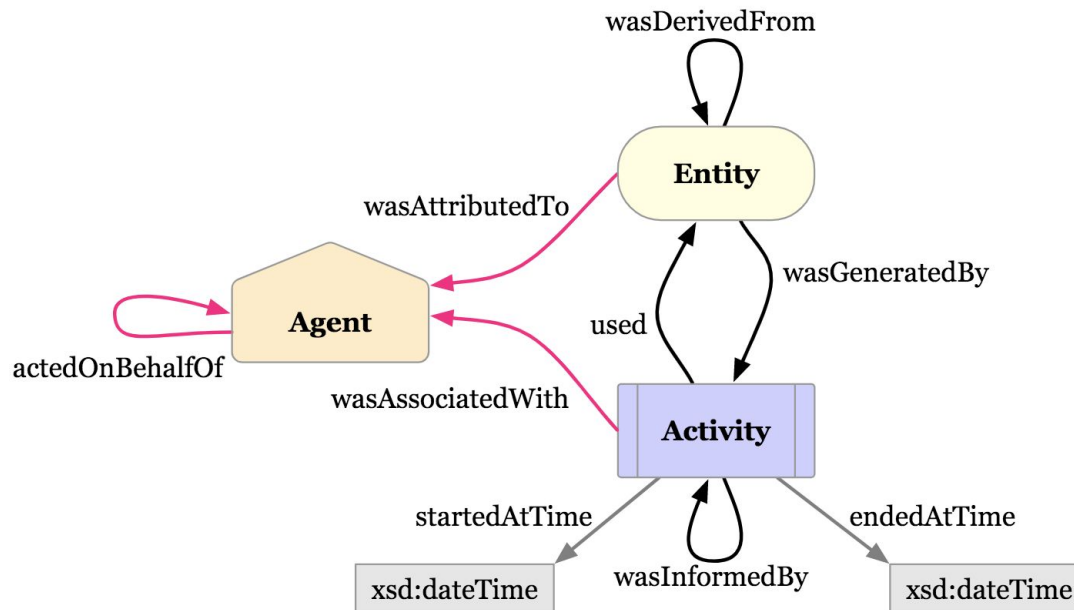

Figure 1. The three Starting Point classes and the properties that relate them. The diagrams in this document depict Entities as yellow ovals, Activities as blue rectangles, and Agents as orange pentagons. The responsibility properties are shown in pink.

<https://www.w3.org/TR/prov-o/>

USGS Hybrid Experiment

GNIS Linked Data

The Linked Data version of the USGS GNIS.

A description of the source dataset from [the Board on Geographic Names](#):

The Geographic Names Information System (GNIS) is the Federal and national standard for geographic nomenclature. The U.S. Geological Survey developed the GNIS in support of the U.S. Board on Geographic Names as the official repository of domestic geographic names data, the official vehicle for geographic names use by all departments of the Federal Government, and the source for applying geographic names to Federal electronic and printed products.

The GNIS contains information about physical and cultural geographic features of all types in the United States, associated areas, and Antarctica, current and historical, but not including roads and highways. The database holds the Federally recognized name of each feature and defines the feature location by state, county, USGS topographic map, and geographic coordinates. Other attributes include names or spellings other than the official name, feature designations, feature classification, historical and descriptive information, and for some categories the geometric boundaries.
